**Open science: a growth opportunity for  
geographical psychology**

**Silviu Matu, Ph.D.**

**[silviu.matu@ubbcluj.ro](mailto:silviu.matu@ubbcluj.ro)**

- The modern „roots” of geographical psychology:

- Variations within-country are smaller than variations between countries (Welzel, 2013);

# Introduction

- Country-level differences in psychological characteristics:
  - Basic psychological characteristics, such as personality traits are similar and can be measured across countries (McCrae et al., 2005a; Schmitt et al., 2007);
    - Similar factor structure; similar age differences; similar pattern of associations.
  - Aggregated scores can be used as descriptors for the psychological profile of a certain country (McCrae et al., 2005b);
    - Culture does not alter the factor structure; convergence of different regions; correlates with other cultural characteristics.
    - Some psychological characteristics (e.g., personality traits) seem to be clustered.
- These characteristics are related to important indicators of country level functioning (psychological, economical and societal; PESH; Rentfrow, 2020).

# Personality Profiles of Cultures: Aggregate Personality Traits

Robert R. McCrae and Antonio Terracciano  
National Institute on Aging, National Institutes of Health,  
Department of Health and Human Services

# Geographical psychology

- *Geographical psychology* is an emerging subarea of research concerned with the spatial organization of psychological phenomena and how individual characteristics, social entities, and physical features of the environment contribute to their organization (Rentfrow & Jokela, 2016).
  - A complex interaction between physical (and biological), social, economic and psychological characteristics;
  - Multiple possible casual pathways on a large historical time-frame (e.g., Chiao & Blizinsky, 2010);
  - Not restricted to country-level analysis.

**Fig 1. Heat maps of the geographical distribution of personality in Great Britain by LAD.** (A) Regional differences in Extraversion. (B) Regional differences in Agreeableness. (C) Regional differences in Conscientiousness. (D) Regional differences in Neuroticism. (E) Regional differences in Openness. For each personality trait, the areas in blue are comparatively low and the areas in red are comparatively high.

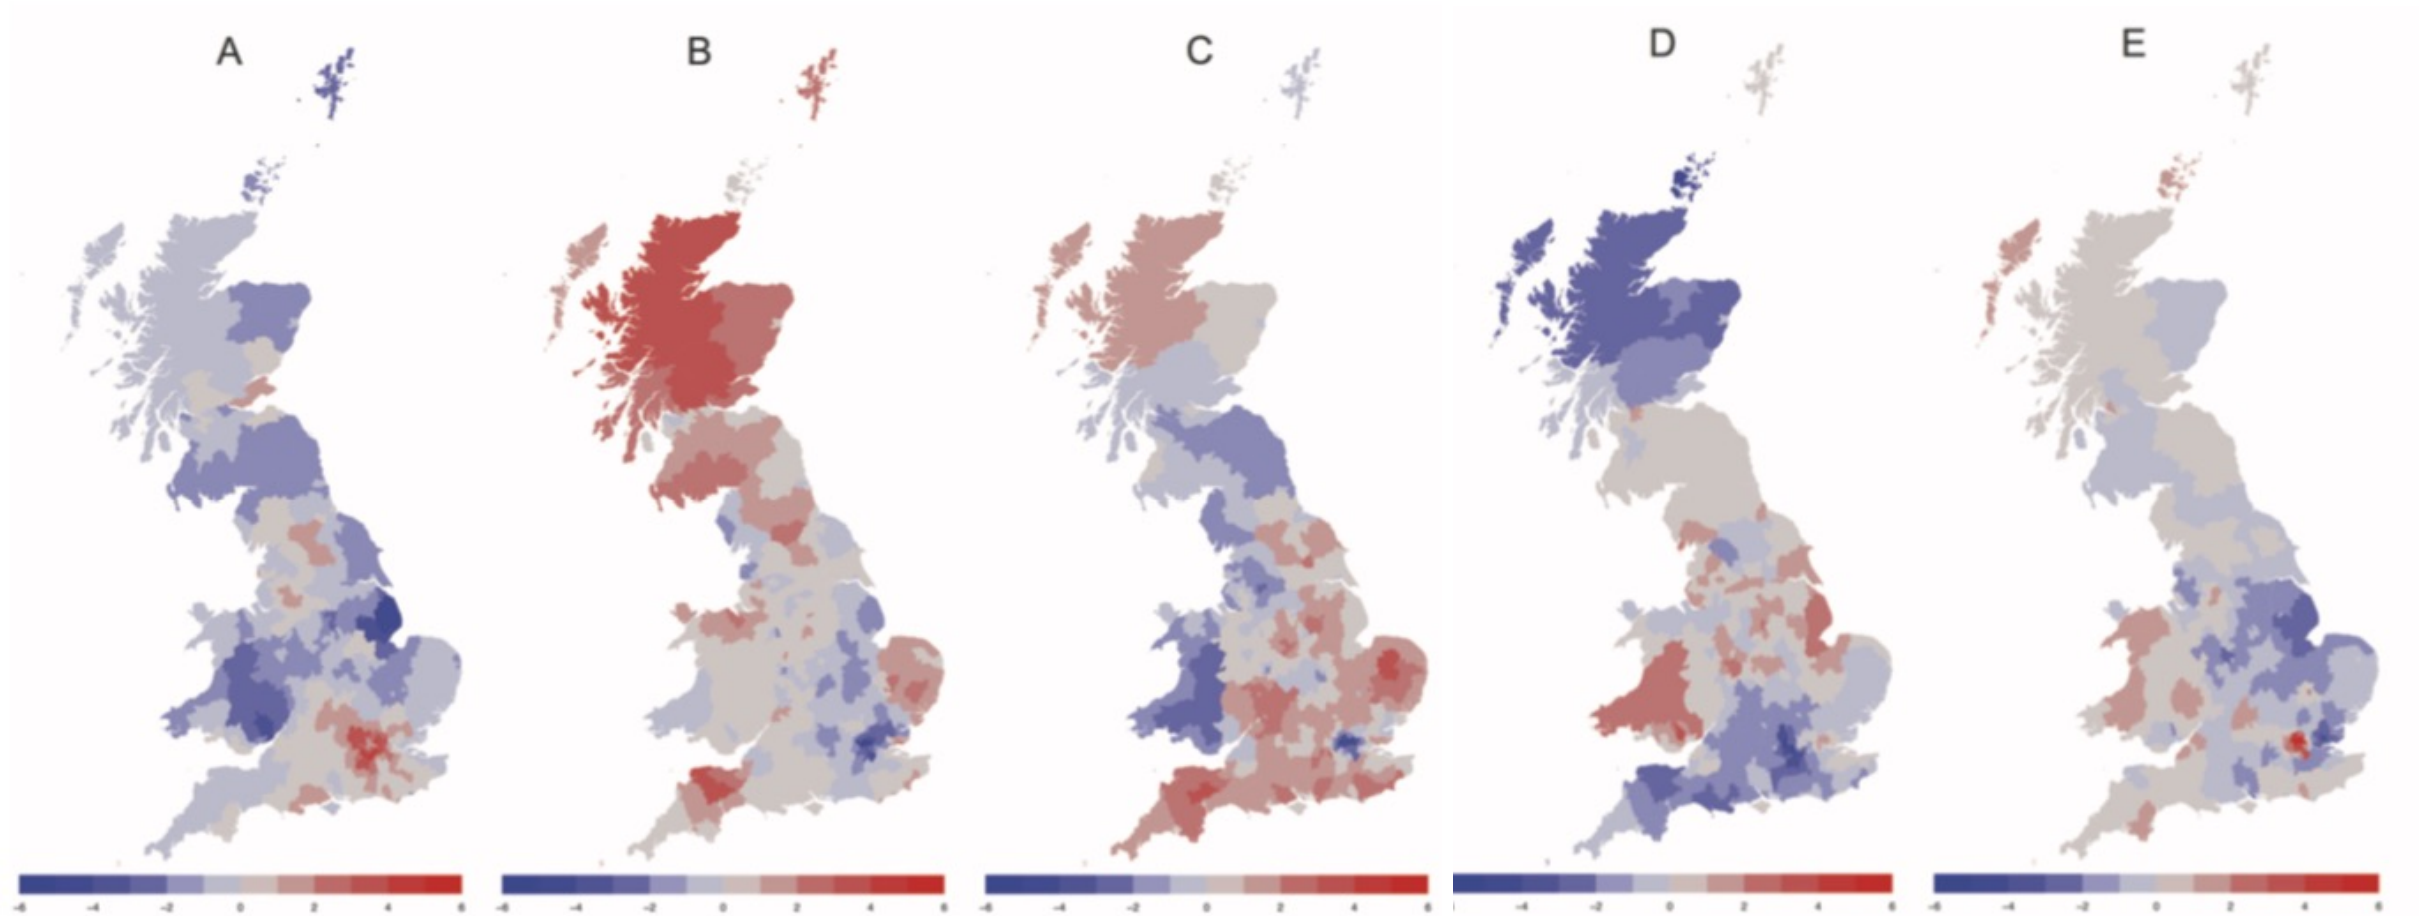

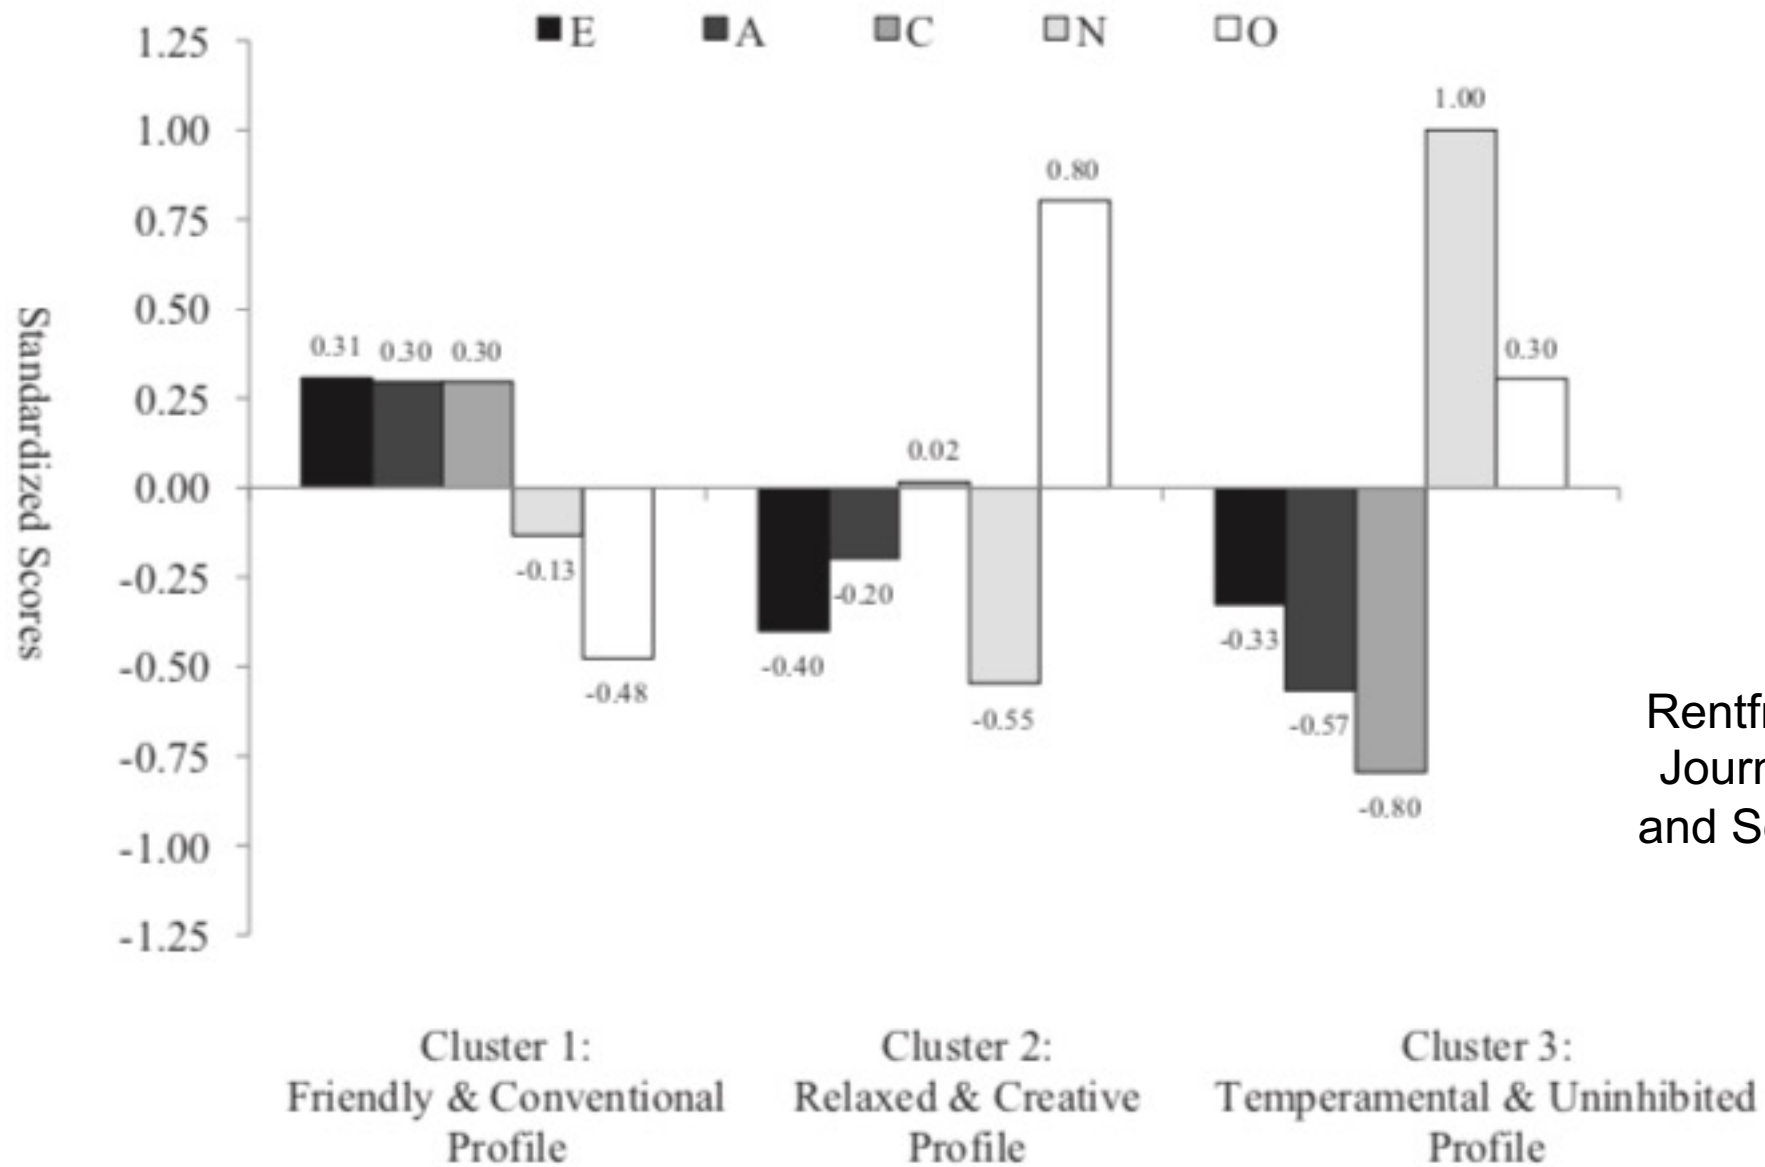

Table 4. Associations between Personality and Demographic, Political, Economic, Social, and Health indicators at the LAD.

Geographical indicators	Extraversion		Agreeableness		Conscientiousness		Neuroticism		Openness	
	<i>r</i>	<i>pr</i>	<i>r</i>	<i>pr</i>	<i>r</i>	<i>pr</i>	<i>r</i>	<i>pr</i>	<i>r</i>	<i>pr</i>

# Problems & opportunities

- Casual mechanism are little explored (and probably difficult to);
  - We need both data, but also theory; complex interactions are largely unexplored.
- A new way in which psychological science could inform policy making.
- We need large & representative data-sets, that are standardized (including geographical location), easily available, at country- and regional level resolution.
- WVS & Open-Source Psychometrics Project are great examples from cross-cultural and personality psychology;
  - Some are not representative or are missing location information (we need more than just country, for many research questions).

# Open Science

- Always make your dataset available, as detailed as possible, including location information.
  - Wasteful science: large representative samples that have unavailable data.
- Not just psychological measures, but also, biological, social, economic, historical and geographical information.
- Integration it is very difficult and challenging: share the integrated data set; make your data available to the public and policy makers in a way that they can use it.

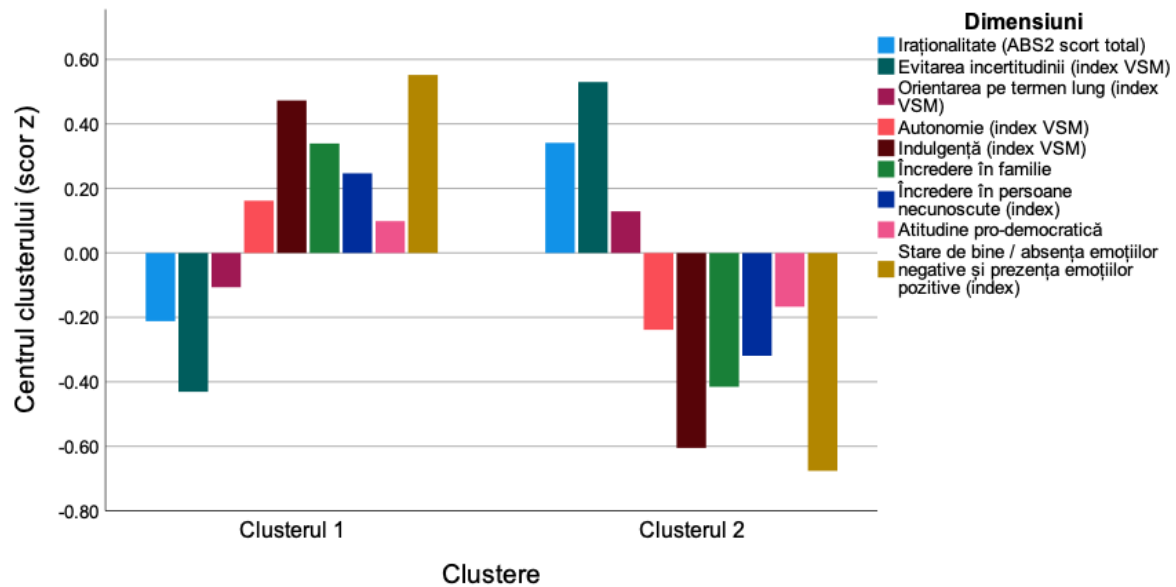

# The ROPSY project & dataset

- The project “Understanding and modeling time-space patterns of psychology-related inequalities and polarization” (PI: Prof. D. David): <http://ropsy.granturi.ubbcluj.ro/>
- Psychological & cultural (CAPI; national representative sample but not regional):
  - 1<sup>st</sup> wave: N = 3025; 2<sup>nd</sup> wave: N = 1950 (longitudinal design; wave 2 not yet integrated)
  - Psychological: Hofstede’s cultural dimensions; rational & irrational beliefs; positive and negative emotions; negative life events; life satisfaction; democratic attitudes;
- Sustainable developmental goals (e.g., mobility and accessibility related to road infrastructure), spatial and economic inequality (e.g., GINI based on night lights); up to 90 indicators;
- Economic indicators: local GDP and GINI-like measures (based on taxation reports).

# The Protective Effect of Culture on Depression During Covid-19 Pandemic: A Romanian National Study

Journal of Cross-Cultural Psychology  
2022, Vol. 53(9) 1166–1186  
© The Author(s) 2022  
Article reuse guidelines:  
sagepub.com/journals-permissions  
DOI: 10.1177/00220221221109564  
journals.sagepub.com/home/jcc

## Abstract

Previous studies indicated that collectivism represents a protective factor against depressive disorders, even among vulnerable populations. The protective effect of collectivism in relation to depressive disorders is often attributed to the social support networks available to individuals in collectivistic societies. The current study aims to investigate the protective effect of collectivism in the relationship between psychological vulnerabilities and depression. Moreover, we examined whether the protective effect of collectivism in relation to depression can be explained through the mechanism of social support. We measured individualism-collectivism for 42 Romanian counties ( $n = 2,882$ ) before the onset of the COVID-19 pandemic. Data for irrational cognitions, depression, and social support were collected online during the lockdown in Romania ( $n = 5,310$ ). All instruments showed acceptable measurement and scalar invariance across regions. In a multi-level regression model, county-level collectivism was associated with lower levels of depressive symptoms  $b = -.032$ , 95% CI  $[-0.045; -0.019]$ , while irrational cognitions were positively associated with depression  $b = .474$ , 95% CI  $[0.438; 0.510]$ . The interaction between irrational beliefs and collectivism had a significant and negative effect on depression,  $b = -.004$ , 95% CI  $[-0.008; -0.000]$ . The indirect effect of collectivism on depression via social support was tested in a two-level SEM model. Explicit and implicit social support were not significant mediators. Collectivism was negatively associated with the perceived availability of explicit social support,  $b = -.043$ , 95% CI  $[-0.074; -0.012]$ . The results support a general protective effect of collectivism on mental health but cast doubt that the mechanism for this effect is related to social support.
